

COMP 530

Introduction to Operating Systems

HW 5

Building a Distributed Linux Shell

A Distributed Linux Shell

A message passing via sockets example

- ◆ Goal: Learn the socket interface and messaging over sockets
 - » Control your shell program remotely from a second machine
- ◆ Same basic structure as HW2:
 - » Write a program that reads a command line from *stdin*
 - ❖ Print a prompt (“% ” — a percent sign followed by a space)
 - ❖ Read a command
 - » Create a child process to parse and execute the command
 - » Parent process just waits for the child to terminate
- ◆ But now the “child” is a process created by a server process on a remote machine

2

Review of HW 4

Linux Interprocess Communication (IPC)

- ◆ IPC in Linux is like message passing except more general
- ◆ The programming abstraction is a “pipe” — a shared, in-memory file
 - » A queue of 4K bytes
 - » Linux *read/write* systems calls used to “pass messages” between processes

3

Review of HW 4

Linux Interprocess Communication (IPC)

- ◆ Pipes provide a form of buffered, asynchronous message passing
 - » Data written to one end of the pipe by one process can be read at the other end of the pipe by another process
 - ❖ A reader of the pipe blocks when the queue is empty
 - ❖ A writer to the pipe blocks when the queue is full
 - » Data is handled in a FIFO (first-in-first-out) order
 - » Pipes are unidirectional

4

Review of HW 4

Linux Interprocess Communication (IPC)

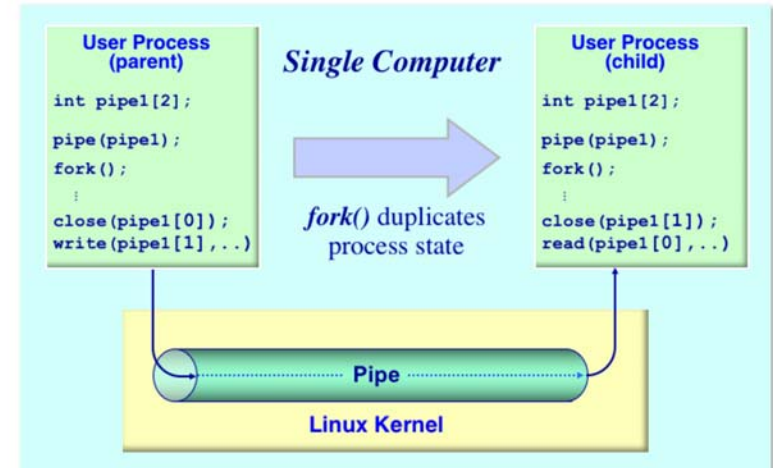

- ◆ Typically, a process creates a pipe just before it forks one or more child processes
 - » Creating a pipe results in a process receiving a read file descriptor and a write file descriptor
- ◆ The pipe is then used for communication between the parent and child process, or between two sibling processes
 - » One process uses the read file descriptor (and ignores the write descriptor) and a second process uses the write file descriptor (and ignores the read descriptor)

Linux Pipes

Programming details

Client/Server Paradigm

Socket programming

- ◆ Sockets are the fundamental building block for client/server systems
- ◆ Sockets are created and managed by applications
 - » Strong analogies with files
- ◆ Two types of transport services are available via the socket API:
 - » UDP sockets: unreliable, datagram-oriented communications
 - » TCP sockets: reliable, stream-oriented communications

socket

a *host-local, application created/released, OS-controlled* interface into which an application process can *both send and receive* messages to/from another (remote or local) application process

©2017 by Kevin Jeffay 8

Client/Server Paradigm

Socket-programming using TCP

- ◆ A socket is an application created, OS-controlled interface into which an application can both send and receive messages to and from another application
 - » A “door” between application processes and end-to-end transport protocols

©2017 by Kevin Jeffay

9

Socket-programming using TCP

TCP socket programming model

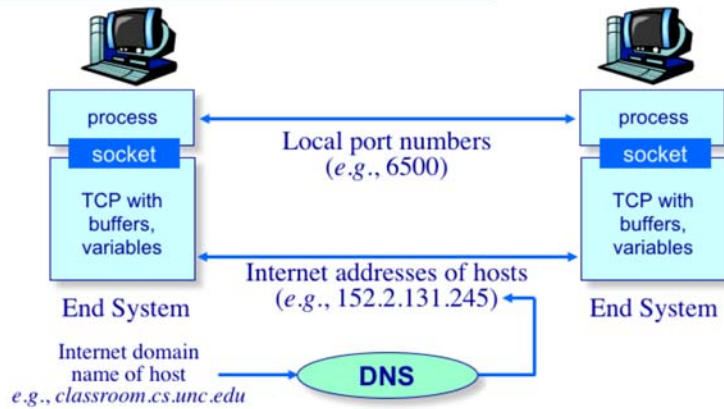

- ◆ A TCP socket provides a reliable bi-directional communications channel from one process to another
 - » A “pair of pipes” abstraction

©2017 by Kevin Jeffay

10

Socket-programming using TCP

Network addressing for sockets

- ◆ Sockets are addressed using an IP address and port number

©2017 by Kevin Jeffay

11

Socket-programming using TCP

Socket programming

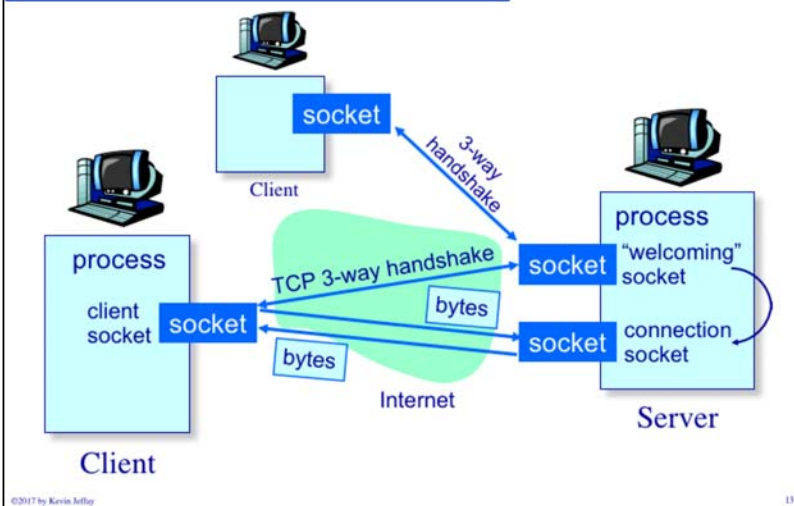

- ◆ Client creates a local TCP socket specifying the host and port number of server process
 - » Host names resolved to IP addresses using DNS
- ◆ Client contacts server
 - » Server process must be running
 - » Server must have created socket that "welcomes" client's contact
- ◆ When the client creates a socket, the client's TCP establishes connection to server's TCP
- ◆ When contacted by a client, server creates a new socket for server process to communicate with client
 - » This allows the server to talk with multiple clients

Socket-programming using TCP

Socket creation in the client-server model

Socket-programming using TCP

Simple client-server example

Socket programming with TCP Example

Client/server TCP socket interaction

Server (running on *snapper.cs.unc.edu*)

```
create socket for incoming
connections(port=6789)
welcome_socket = new ServerSocket_new(6789)
```

```
wait for incoming
connection request
connect_socket =
ServerSocket_accept(welcome_socket)
```

```
read/get request from
connect_socket
```

```
write/put reply to
connect_socket
```

```
close
connect_socket
```

Client (running on *classroom.cs...*)

```
create socket,
connect to snap.cs.unc.edu, port=6789
connect_socket = Socket_new(...)
```

```
write/put request using
connect_socket
```

```
read/get reply from
connect_socket
```

```
close
connect_socket
```
